Completed:

Metadata 101 – Using Attributes in Creo Illustrate

Intro

In today's world where so many companies are mostly virtual, it can prove at times to be hard to understand a physical product without having that part in front of a person. The sales, marketing, and service organizations of these companies need a way to digitally display these models for product familiarization, which is where AR and Vuforia Studio come in. Using Vuforia Studio, you can create AR representations of your products that are interactive and can display part data when clicked on. This allows you to give interactive product demonstrations and explain service procedures without ever needing the physical part in front of you.

This portion of the project will help you become familiar with the added functionality that JavaScript coding can add to a Vuforia Studio experience regarding populating Ionic popovers with information and highlighting parts based on user clicks. It will cover the following topics:

[Metadata 201.1 Set Up the Project](#)

[Metadata 201.2 Userpick Events with an Ionic Popup](#)

[Metadata 202.3 Add Attributes from a Model to the Ionic Popup and Highlighting](#)

[Metadata 202.4 Bind the Play and Reset Buttons](#)

[Metadata 202.5 Highlight Parts](#)

These sections can all be easily accessed using their hyperlinks.

There are also 8 appendices at the end of the document for code explanation and copying.

All important notes and UI areas are **Bold**

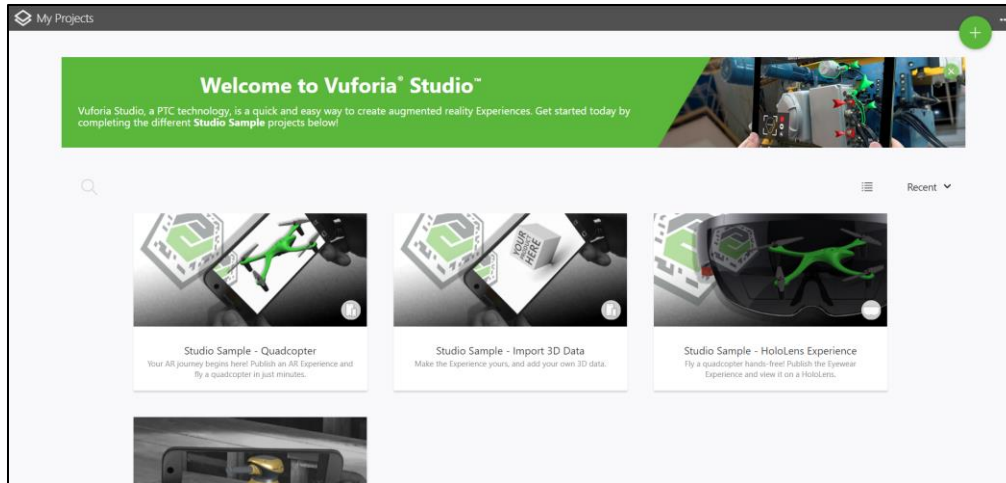

All non-code text to be typed is *italicized*

All code follows `this convention`

All code comments follow `this convention`

201.1 Set Up the Project

1. Open Vuforia Studio.

2. If not already configured, click the ... at the top-right corner of the screen, select **Settings**, and add an **Experience Server** in the **Default Experience Server URL** box.
3. Click the **+** in the top-right corner to create a new project.
4. Select the **Mobile** template.
5. In the **New Project** box, enter *Metadata200* in the **Project Name** field and confirm that the correct **Experience service URL** is being used. This project will be used for both the Metadata 201 and Metadata 202 tutorials.

New Project

Project Name

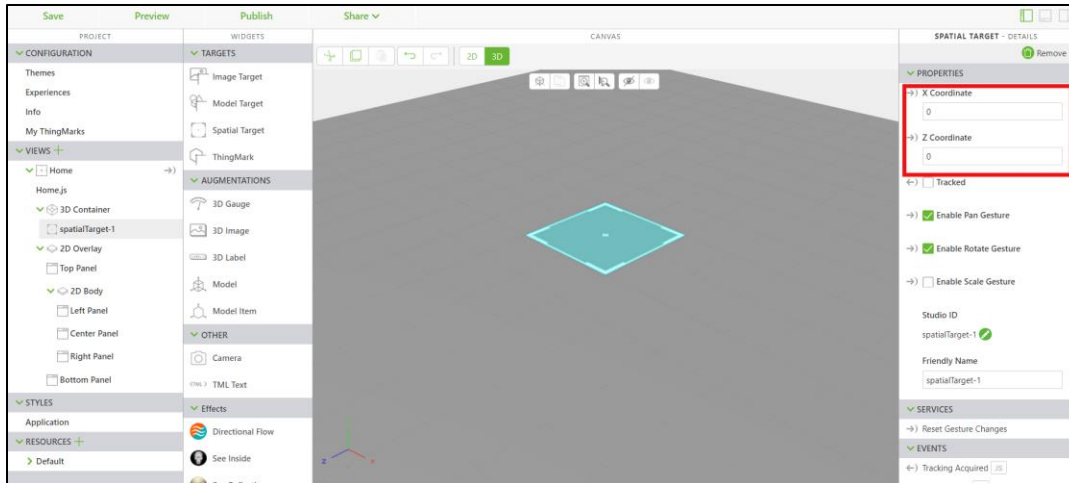

Experience service URL

✓

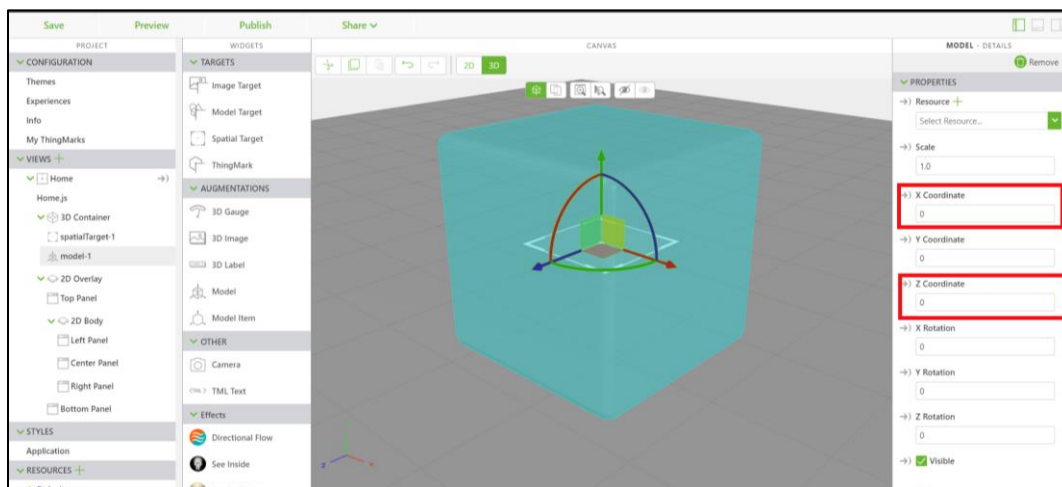

Create

[Cancel](#)

6. Drag and drop a **Spatial Target** onto the 3D canvas. Set the **X Coordinate** and **Z Coordinate** properties to *0*.

7. Drag and drop a **Model** widget onto the canvas. Set the **X Coordinate** and **Z Coordinate** properties to 0 so that the model widget is in line with the **Spatial Target**. This is important, as a misaligned model can cause issues when viewed as an AR experience.

8. In the **Properties** pane for the **Model** widget, select **Resource +** to add a model to the widget. Browse to and select the completed quadcopter.pvz model that was created in Metadata 101. Check the box for **Allow the Experience access to CAD metadata**; this keeps the metadata attributes that are associated with the model from Creo Illustrate during the import process. Leave **Run CAD Optimizer** unchecked, as it will take away its underlying attributes. Click **Add**.

Add Resource

For a list of supported formats, see [Supported CAD File Formats](#)

Select File

quadcopter.pvz

☐ Run CAD Optimizer

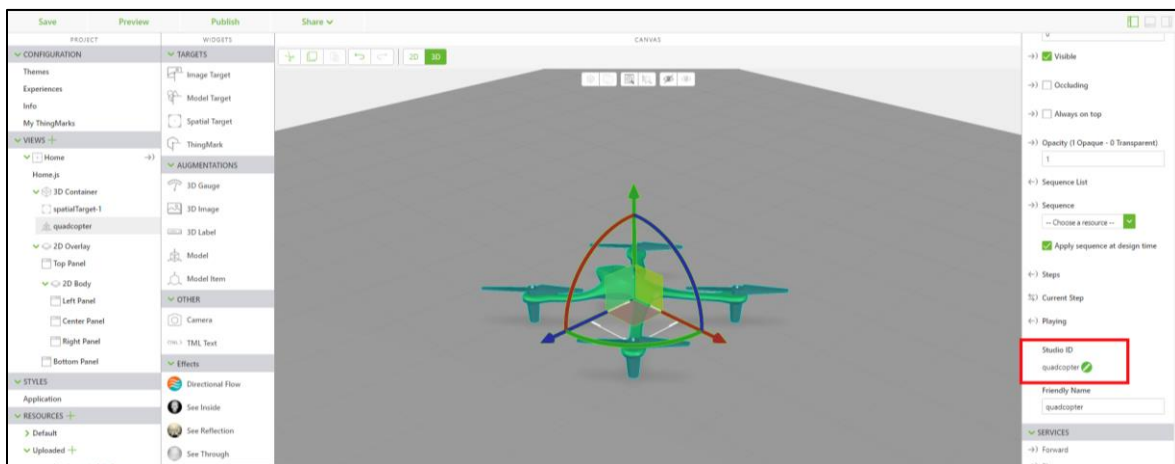

Upon adding your 3D file, Vuforia Studio will convert it to a pvz. Please check "Run CAD Optimizer" if you would like to generate optimized files.

☒ Allow the Experience access to CAD metadata.
For more information, see the [Resources](#) topic in the Help Center.

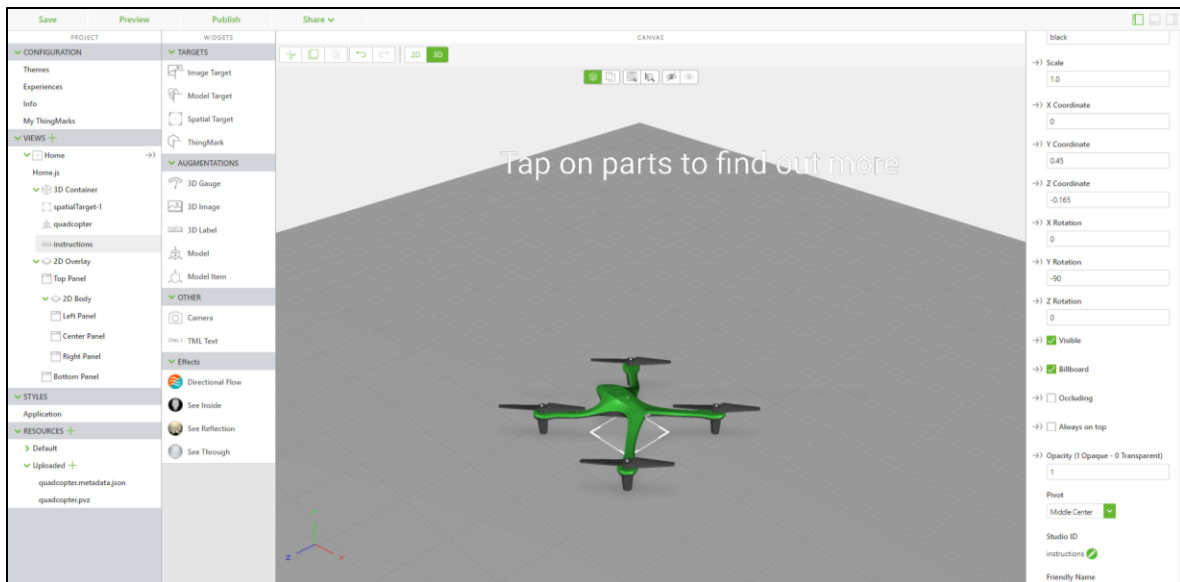

Add

[Close](#)

9. With the quadcopter model now visible on the canvas, change the **Studio ID** property to *quadcopter*.

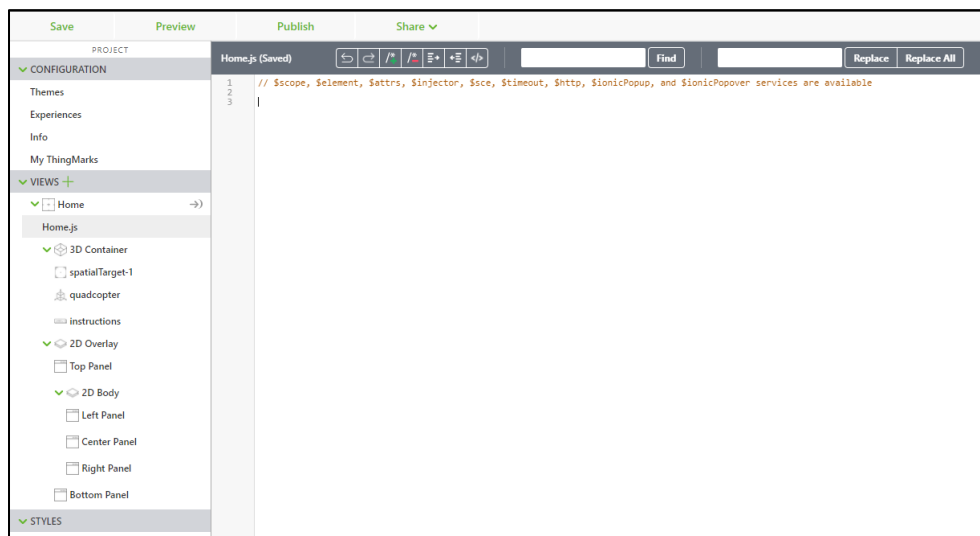

10. Add a **3D Label** widget onto the canvas.
 - a. Change the **Text** property to say *Tap on parts to find out more*.
 - b. Set the **Font Color** property to *white* and **Font Outline Color** to *black*.
 - c. Change the **X, Y, and Z Coordinate** properties to *0, 0.45, and -0.165*, respectively.
 - d. Set the **X Rotation** property to *0* and **Y Rotation** to *-90*.
 - e. Check the box for the **Billboard** property. This property ensures that the label is always flat to the viewing device, regardless of orientation of the viewer.
 - f. Change the **Studio ID** for this widget to *Instructions*.

102.2 Userpick Events with an Ionic Popup

In addition to being able to bind widget events to custom JavaScript code in the **Events** section of the Property pane, JavaScript code can be written in the **Home.js** view for more complex custom coding. This section uses the **userpick** event listener function to signal an Ionic Popover to appear when a part of the quadcopter is selected.

1. Open the **Home.js** view in the **Project** pane. This is where the custom JavaScript code can be written.

2. The first lines of code to be added will be an event listener for when users tap on the model. An event listener is a function that is triggered when a certain event occurs. Vuforia Studio has a 3D object related event called **userpick** that is triggered when a user clicks on a part of the quadcopter in Vuforia View. Additional event listeners are available in [Appendix 1](#), [Appendix 2](#), and [Appendix](#)

3. For the arguments in this case, `event` is the act of clicking, `targetName` is referencing the name of the selected model, `targetType` corresponds to the type of widget that is being selected, and `eventData` is a JSON object with the occurrence property, which gives the **Model Tree** location of the selected part.

```
$scope.$on('userpick', function (event, targetName, targetType, eventData) {  
  }) //end brackets for userpick function. Will continue to move throughout code
```

3. Next, inside the `userpick` event, add the code for what should happen when the user picks something. The `eventData` argument that is returned is a part-specific JSON object. It contains data about the selected target, much like a **Model Item** would if it were added to a model. One of the object properties that is returned is the **occurrence** of the model, set to the `pathId` variable, which gives the **Model Tree** location of the selected part and is used to differentiate parts from one another. This is how Studio can differentiate between the parts that the user clicks on. In this case, an **Ionic popup** should appear. Ionic is a cross-platform SDK for web developers to assist with building applications. An Ionic popup is a dialog box that appears on the screen when a part is clicked. This is used to display part information in the next section.

```
//  
// variable to pull the value for the occurrence property in the eventData JSON object  
from the model  
var pathId = JSON.parse(eventData).occurrence
```

```
// adds an ionic popup when a part is clicked. Show the pathId of the selected object  
var popup = $ionicPopup.show({  
  template: '<div>' + pathId + '</div>',  
  scope: $scope  
}); //end of ionic popup
```

```
1 // $scope, $element, $attrs, $injector, $sce, $timeout, $http, $ionicPopup, and $ionicpopup services are av  
2  
3 $scope.$on('userpick', function (event, targetName, targetType, eventData) {  
4   //  
5   // variable to pull the value for the occurrence property in the eventData JSON object from the model  
6   var pathId = JSON.parse(eventData).occurrence  
7  
8   // adds an ionic popup when a part is clicked. Show the pathId of the selected object  
9   var popup = $ionicPopup.show({  
10    template: '<div>' + pathId + '</div>',  
11    scope: $scope  
12  }); //end of ionic popup  
13  
14 }) //end brackets for userpick function. Will continue to move throughout code
```

4. **Progress Check:** Click **Save** to update the project and then **Preview** in Studio to open a preview of the experience so far. Click on any part of the quadcopter. A **popup** should appear in the preview window with the occurrence path of the part. If nothing pops up, double check that the code has been copied correctly.

5. Finish this by adding in a function that will cause the popup to close on its own, which will come directly after the code for showing the popup

```
// create a function to close the popup.
var closePopup = function (popup) {
  //
  // function for returning that the popup will be closed using the .close() method
  return function() {
    //
    //close the popup
    popup.close()
  } // return end
} // closepopup function end

//call the $timeout service which will call the function for closing the popup after 3
seconds (3000 ms)
$timeout(closePopup(popup), 3000);

12    }); //end of ionic popup
13
14    // create a function to close the popup.
15    var closePopup = function (popup) {
16      //
17      // function for returning that the popup will be closed using the .close() method
18      return function() {
19        //
20        //close the popup
21        popup.close()
22      } // return end
23    } // closepopup function end
24
25    //call the $timeout service which will call the function for closing the popup after 3 seconds (3000 ms)
26    $timeout(closePopup(popup), 3000);
27
28    }) //end brackets for userpick function. Will continue to move throughout code
```

6. Click **Save** and open the **Preview** tab once again. Click on the quadcopter. If a popup appears and then disappears in 3 seconds, then this section has been completed correctly. The completed code for this section is available in [Appendix 4](#).

201.3 Add Attributes from a Model to the Ionic Popup and Highlighting

Once an Ionic popup has been successfully created, you can add the Attribute metadata that was created for the model in Creo Illustrate in the Metadata 101 portion

of this project. This is achieved by using the **PTC Metadata API** which is now included in versions 8.5.13 and beyond of Vuforia Studio.

1. Use the **PTC Metadata API** to call the Attributes from the JSON data for the model. This version of the API uses a `.then` method to that will use a callback function to retrieve the data if there is metadata for the model.
 - a. Navigate to **Home.js** and add this code directly below the `userpick` function:

```
//  
//Look at model and see if it has metadata. If it does, then execute the below code and  
create an object called metadata  
PTC.Metadata.fromId(targetName)  
    .then ( (metadata) => {
```

- b. Indent **lines 8-30** by selecting them and clicking the **Indent** button. These lines will be placed inside of the PTC API above, as they are dependent on the promise being successful.

- c. Add the below code to **line 32** to put some bracket ends on the PTC API function. This ensures that there are no errors with unfinished lines.

```
}) //end brackets for PTC API and .then  
//catch statement if the promise of having a part with metadata is not met  
.catch( (err) => { console.log('metadata extraction failed with reason : ' +err) })
```

```
1 // $scope, $element, $attrs, $injector, $sce, $timeout, $http, $ionicPopup, and $ionicpopup services are available  
2  
3 $scope.$on('userpick', function (event, targetName, targetType, eventData) {  
4     //  
5     //Look at model and see if it has metadata. If it does, then execute the below code and create an object called metadata  
6     PTC.Metadata.fromId(targetName)  
7     .then((metadata) => {  
8         //  
9         // variable to pull the value for the occurrence property in the eventData JSON object from the model  
10        var pathId = JSON.parse(eventData).occurrence  
11  
12        // adds an ionic popup when a part is clicked. Show the pathId of the selected object  
13        var popup = $ionicPopup.show({  
14            template: '<div>' + pathId + '</div>',  
15            scope: $scope  
16        }); //end of ionic popup  
17  
18        // create a function to close the popup.  
19        var closePopup = function (popup) {  
20            //  
21            // function for returning that the popup will be closed using the .close() method  
22            return function() {  
23                //  
24                //close the popup  
25                popup.close()  
26            } // return end  
27        } // closepopup function end  
28  
29        //call the $timeout service which will call the function for closing the popup after 3 seconds (3000 ms)  
30        $timeout(closePopup(popup), 3000);  
31  
32    }) //end brackets for PTC API and .then  
33    //  
34    //catch statement if the promise of having a part with metadata is not met  
35    .catch((err) => { console.log('metadata extraction failed with reason : ' + err) })  
36  
37 }) //end brackets for userpick function. Will continue to move throughout code
```

2. Uncovering the data from the metadata attributes requires the `get` function for the PTC Metadata API. Calling `metadata.get` retrieves all metadata for the model, which in this case is comprised of the attributes of the part that were added in Creo Illustrate. Using the `pathID` variable, which contains the **occurrence** data of

the, causes the `metadata.get` function to index the data for the selected part. A full list of metadata API functions can be found on the [PTC Support Website](#) of this document. This function is used to obtain values for the following variables: the display name of the part, the instruction name, and the part number. Add the following code below the `pathId` variable:

```
// create variables based on attribute names from Creo Illustrate for this model. use
metadata.get to obtain the data from the JSON properties for this occurrence.
```

```
var partName = metadata.get(pathId, 'Display Name');
var instructionName = metadata.get(pathId, 'Illustration');
var partNumber = metadata.get(pathId, 'partNumber');
```

```
1 // $scope, $element, $attrs, $injector, $sce, $timeout, $http, $ionicPopup, and $ionicpopup services are
2
3 * $scope.$on('userpick', function (event, targetName, targetType, eventData) {
4 //
5 // Look at model and see if it has metadata. If it does, then execute the below code and create an object
6 PTC.Metadata.fromId(targetName)
7 * .then((metadata) => {
8 //
9 // variable to pull the value for the occurrence property in the eventData JSON object from the model
10 var pathId = JSON.parse(eventData).occurrence
11
12 // create variables based on attribute names from Creo Illustrate for this model. use metadata.get to
13 var partName = metadata.get(pathId, 'Display Name');
14 var instructionName = metadata.get(pathId, 'Illustration');
15 var partNumber = metadata.get(pathId, 'partNumber');
```

3. Change the definition for the `template` property of the popup. Now that the attribute data has been imported into Studio, the Ionic popup should display the `partNumber` and `partName` variable values when clicked on. The comment has also been edited to include more information

```
// adds an ionic popup when a part is clicked. Show the part number and name of the
selected object. &nbsp;<br> adds a line break between the two variables
```

```
var popup = $ionicPopup.show({
  template: '<div>' + partNumber + '&nbsp;<br>' + partName + '</div>',
  scope: $scope
}); //end of ionic popup
```

```
17 // adds an ionic popup when a part is clicked. Show the part number and name of the selected object. &nbsp;<br>
18 * var popup = $ionicPopup.show({
19   template: '<div>' + partNumber + '&nbsp;<br>' + partName + '</div>',
20   scope: $scope
21 }); //end of ionic popup
```

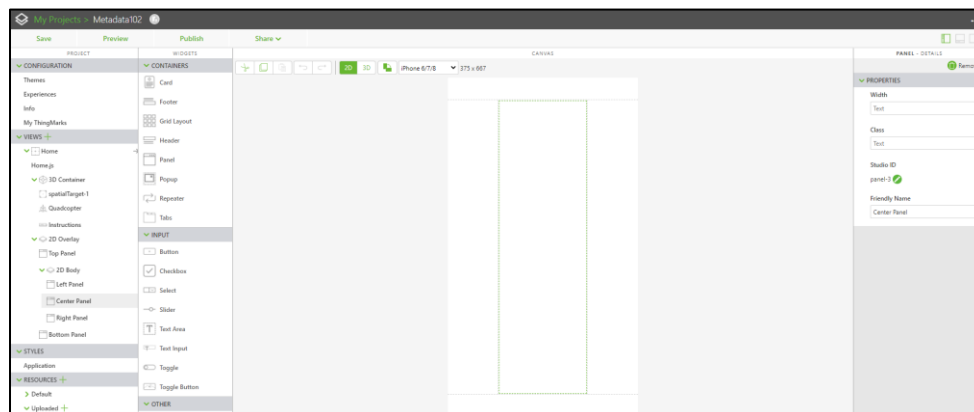

4. Click **Save** and open **Preview** to verify that the new information was added into the popup. If the image looks like the one below, then this step has been completed correctly. The full code up until this section is provided in [Appendix 5](#).

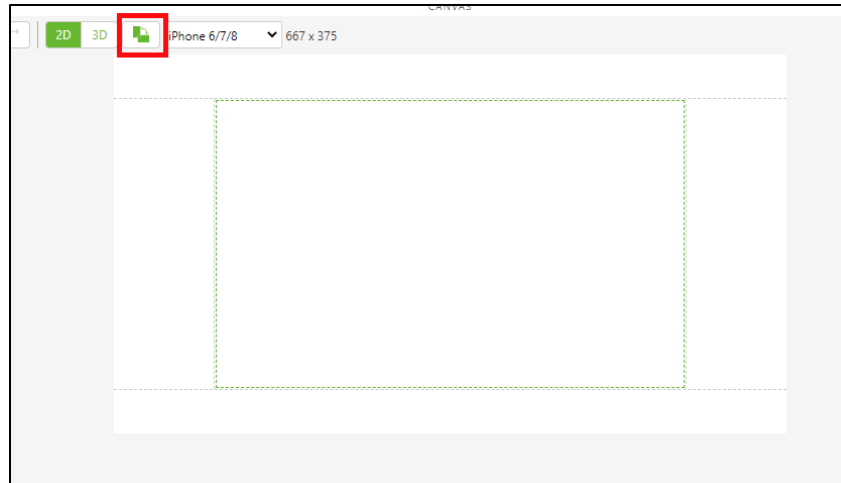

201.4 Bind Play and Reset Buttons

In Metadata 101, illustration sequences were created for the model and the **Illustration** attribute was added to parts associated with the sequence. This attribute will be used to tell Studio which disassembly sequence to display on the model. In this experience, if a selected part has an associated illustration sequence with it, Studio will gather that **Illustration** attribute value and you will be given the option to play the illustration sequence. There will also be a **Reset** button added to the experience to reset the model at any given time. These buttons will be added to the 2D canvas of the experience

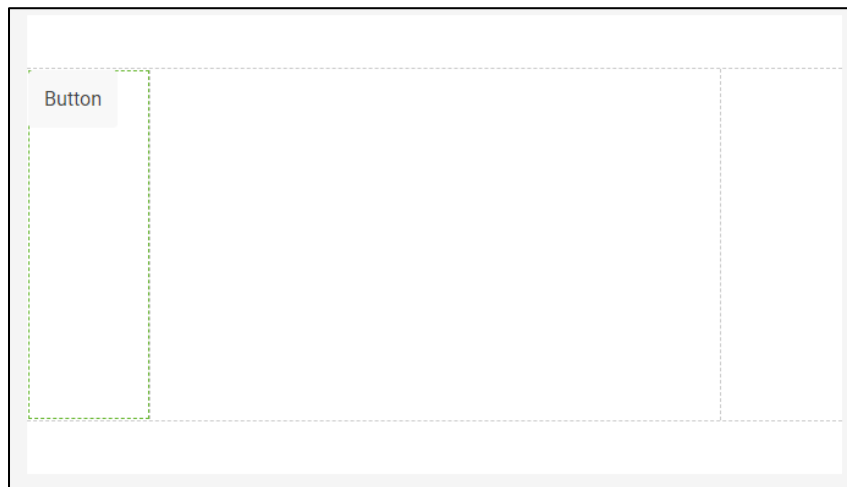

1. Navigate to the **Home** view and open the **2D** canvas.

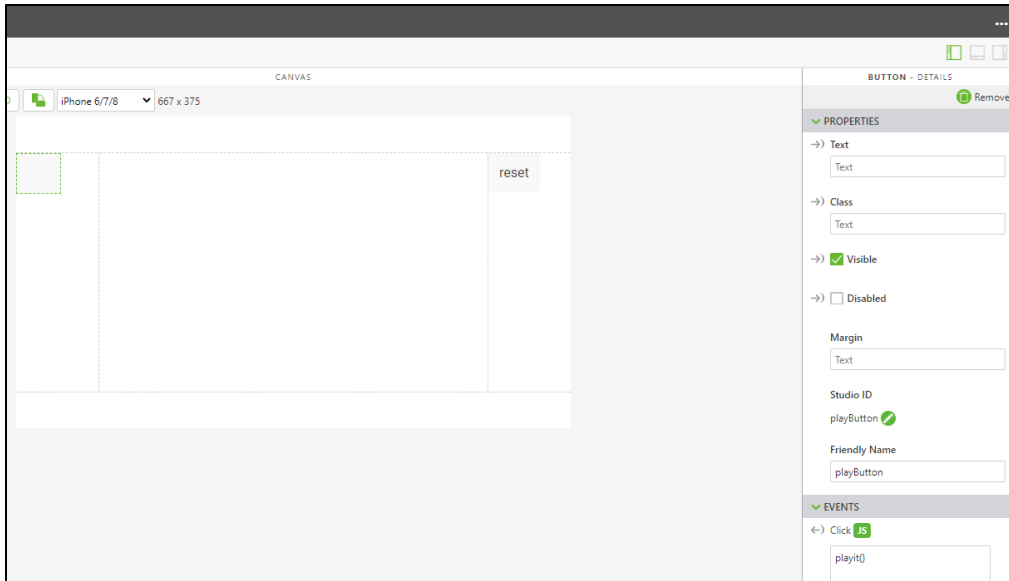

2. Flip the orientation of the 2D canvas. It is suggested that the user viewing the experience is holding the phone or mobile device in a landscape orientation when using this experience.

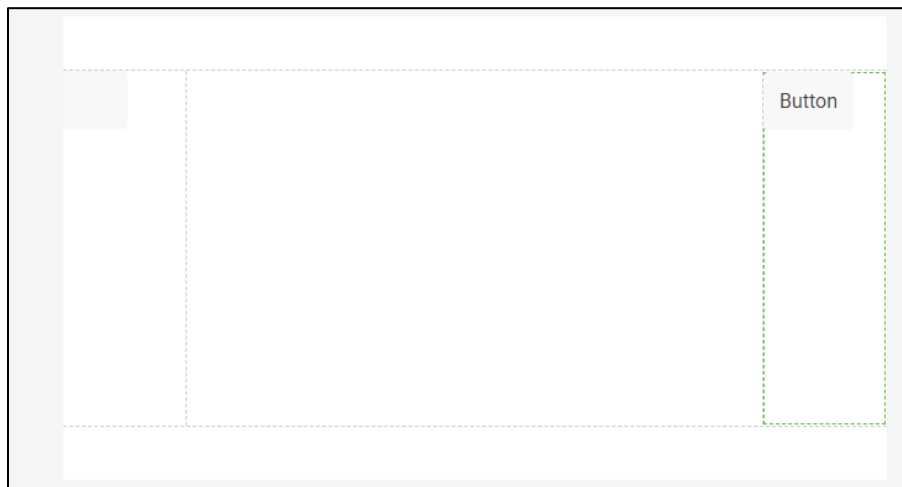

3. Add a **Button** widget to the **Left Panel** of the canvas.

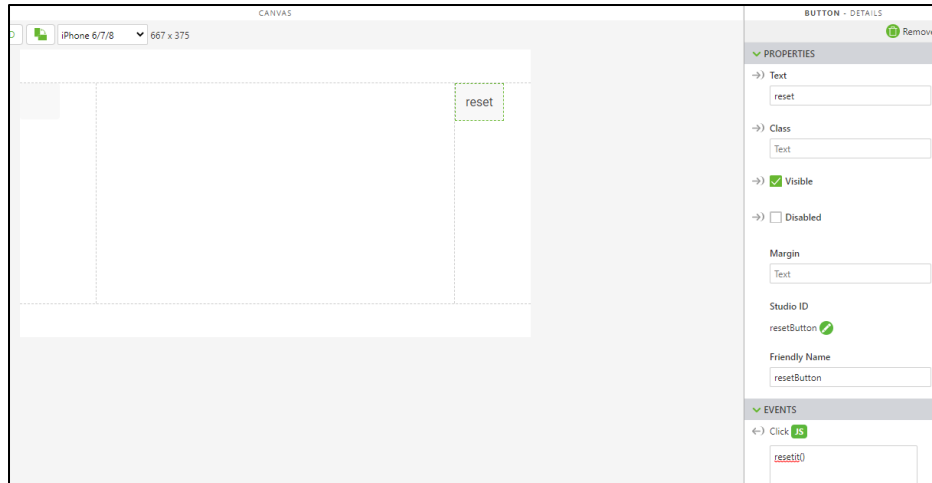

- Remove the text from the **Text** property so that the button is blank.
- Change the **Studio ID** of the button to *playButton*.
- Open the **JS** dialog box for the **Click** event and enter *playit()*. This will bind the button to a function in the **Home.js** section that will be created in a later step.

4. Add another **Button** widget onto the **Right Panel** of the canvas.

- a. In the **Text** property, change the value to *Reset*.
- b. Change the **Studio ID** of the button to be *resetButton*.
- c. In the **JS** box for the **Click** event, enter *resetit()*. This will bind the button to a function in the **Home.js** section that will be created in a later step.

5. Earlier, you created an Ionic popup to display the name and part number of a given part. Another attribute that some parts will have is the **Illustration** attribute that was added in Metadata 101. This attribute contains the name of an animated sequence that was created in Creo Illustrate. A sequence is a combination of steps to perform a certain procedure, and it is transferred in with .pvz files when added into Vuforia Studio. The Play and Reset buttons will allow you to start or reset playback of the sequences associated with the quadcopter model.

Note: The information in this section will only work if the **Illustration** attribute has been filled out correctly for the model. Any part that does not have an **Illustration** attribute will not be able to play a sequence.

- a. After the popup disappears, the **playButton** widget should display the name of the sequence (if applicable) of the selected part. Add the code below inside the **closePopup** function to change the **Text** property of the **playButton** and edit an object called **toPlay** that will hold information about the model. The **toPlay** object will store the name of the model, which is based the **targetName** argument, and the illustration sequence of the model. Illustration sequences are stored as .pvi files inside .pvz files that are created in Creo Illustrate and then imported into Studio with the completed model from Illustrate. The format of these files is 1-Creo 3D- (figure name).pvi (unless the Publish options were changed, in which case Creo 3D may not be the string for the file format.). In this experience, the **instructionName** variable holds the value from the **Illustration** attribute for the selected part for the **Figure** in Creo Illustrate that holds the animated sequence and is called into the string of text that is used to create the **instruction** property in the **toPlay** object.

```
//
//change the Text property of the playButton to the instructionName variable,
which was created from the JSON data of the model
$scope.view.wdg.playButton.text = instructionName;
//
```

```

    /* create an object for the playButton called toPlay. This object will have
    properties of model, which will be the name of the object that is clicked on and
    instruction, which will add the proper syntax for calling a sequence, based off the
    instructionName variable, into Studio*/
    $scope.view.wdg.playButton.toPlay = { model: targetName, instruction: 'l-Creo 3D
- ' + instructionName + '.pvi' };
    //

```

```

30     popup.close()
31     //
32     //change the Text property of the playButton to the instructionName variable, which was created from the JSON data of the model
33     $scope.view.wdg.playButton.text = instructionName;
34     //
35     /* create an object for the playButton called toPlay. This object will have properties of model, which will be the name of the
36     which will add the proper syntax for calling a sequence, based off the instructionName variable, into Studio*/
37     $scope.view.wdg.playButton.toPlay = { model: targetName, instruction: 'l-Creo 3D - ' + instructionName + '.pvi' };
38     //
39     } // return end

```

- b. Click **Save**, open the **Preview** tab, and click on the front-left rotor of the quadcopter when it appears. You should notice the change that happens to the **playButton** after the popup disappears. Try this to other parts and see the difference between ones that have sequences associated with them and the ones that don't.

- c. Now that the text for the button is changed, a function needs to be bound to the button to play the sequence. If you remember, the function named *playit()* was added as a **Click JS** event for the **playButton** widget. This sets the value of the **Sequence** property of the **quadcopter** model to be equal to the **instruction** property of the **toPlay** object of **playButton**. In this case, **quadcopter** in the code below is referencing the name of the **model** widget that was added. If the **Studio ID** of the widget was not changed to *quadcopter* earlier in the project, this code will not work and the name of the model in the code will need to be changed. Place the following at the bottom of the code, as it is a separate function from **userpick**.

```

//create the playit function to bind a sequence for the model to the play button
$scope.playit = function () {
    //

```

```

// if there is information in the created toPlay object to say that there is an
Illustration attribute for the part
if ($scope.view.wdg.playButton.toPlay != undefined)
//
// set the sequence property for the quadcopter model to be equal to the value of the
instruction property of the toPlay object
$scope.view.wdg.quadcopter.sequence = $scope.view.wdg.playButton.toPlay.instruction;
}
50 //end brackets for userpick function. Will continue to move throughout code
51
52 //create the playit function to bind a sequence for the model to the play button
53 * $scope.playit = function () {
54     //
55     // if there is information in the created toPlay object to say that there is an Illustration attribute for the part
56     if ($scope.view.wdg.playButton.toPlay != undefined)
57         //
58         // set the sequence property for the quadcopter model to be equal to the value of the instruction property of the toPlay object
59         $scope.view.wdg.quadcopter.sequence = $scope.view.wdg.playButton.toPlay.instruction;
60 } // playit function end

```

- d. Once the **Sequence** property has been set for the model, the **playButton** widget needs to signal that sequence to start. This can be accomplished by using the **sequenceloaded** event listener and widget service calls, which will start the playback of the sequence. Like in the last step, the **Studio ID** for the **model** widget needs to have been set to *quadcopter*, or else the code will need to be edited.

```

//sequenceloaded event listener triggers when the sequence property is updated
$scope.$on('sequenceloaded', function(event) {
//
// call a widget service to trigger the quadcopter model to play all steps for the
given sequence
twx.app.fn.triggerWidgetService('quadcopter', 'playAll');
}); //serviceloaded event function end

```

```

60 // playit function end
61
62 //sequenceloaded event listener triggers when the sequence property is updated
63 * $scope.$on('sequenceloaded', function(event) {
64     //
65     // call a widget service to trigger the quadcopter model to play all steps for the given sequence
66     twx.app.fn.triggerWidgetService('quadcopter', 'playAll');
67 }); //serviceloaded event function end

```

- e. Similar to the **playButton** widget, the **resetButton** also has a JS event attached to it. This JS event is called *resetit()*. This function resets the model back to its original state, regardless if it is mid-playback or after a finished sequence. This happens by setting the **Sequence** property of the **quadcopter** model to being blank.

```

//resetit function
$scope.resetit = function () {
//
//set the sequence property of the quadcopter model to blank
$scope.view.wdg.quadcopter.sequence = ''
} //resetit function end

```

```

67 //serviceloaded event function end
68
69 //resetit function
70 * $scope.resetit = function () {
71     //
72     //set the sequence property of the quadcopter model to blank
73     $scope.view.wdg.quadcopter.sequence = ''
74 } //resetit function end

```

- f. Once the code has been completely added to **Home.js**, click **Save** and open **Preview**. Click on the front-left rotor. If the popup appears, then the play button is populated with text, and when clicked, starts the repair sequence. If this happens, this has been completed successfully. The full code for this section is in [Appendix 6](#).

102.4 Highlight Parts

This experience uses a dynamic structure for selecting parts on the model. In a Studio context, this means that parts of a model can be selected on their own without the need for a Model Item to separate the parts. Using the **tml3DRenderer**, a Studio renderer based on WebGL, and the **occurrence** data offers users a set of services for changing 3D components based on their node IDs, which is what allows dynamic changes based on which part is selected by the user. This allows the model to be more interactive without needing to add widgets to the experience.

When selected, parts should not only have an Ionic popup appear with their part information, they should also be highlighted. Using JavaScript code and TML Text widgets to create shaders, this section will explain how to do just that.

1. In **Home.js**, a new function for highlighting parts will need to be created. This function will have inputs of **items**, which will be the part that is selected, and **hilite**, which is a Boolean that decides if a part needs to be highlighted. Inside the function, the **tml3DRenderer** object will be edited, which corresponds to the **TML Text** widget that will be added in the next step. The **tml3DRenderer** object calls the **.setProperties** service to set the properties of the object. In this service, it intakes the item that is supposed to be highlighted and then checks to see if the Boolean value **hilite** that has been input to the function is true or not. The **?** conditional operator evaluates if **hilite** is true or false and then returns a set of object properties based on if it is true or false. If **hilite** is true, then the following properties will be set for the object: `{ shader:"green", hidden:false, opacity:0.9,`

`phantom:false, decal:true }`. In this case, *green* is the name given to the **TML Text** widget that will be added to the next step, so this line of code is what calls the TML Text widget to activate. If *hilite* is false, then `{shader:"Default", hidden:false, opacity:1.0, phantom:false, decal:false}` will be set as the properties, which signal the parts to just stay their default views. This portion of the function is editing the graphic interface of Studio using WebGL. This code will not highlight the selected part until the **TML Text** widget is added.

```
//highlight function. Inputs are the selected part and a boolean for hilite
$scope.hilite = function (items, hilite) {
  //
  //iterate over each item that is used as an imported variable for the function using
  .forEach to look at each value that comes in the items input
  items.forEach(function(item) {
    //
    //set the properties of the TML 3D Renderer to highlight the selected item using a TML
    Text shader. "green" is the name of the script for the TML Text.
    tml3dRenderer.setProperties(item, hilite===true ? { shader:"green", hidden:false,
    opacity:0.9, phantom:false, decal:true }
    : {shader:"Default", hidden:false, opacity:1.0,
    phantom:false, decal:false});
  }) //foreach function end
} //hilite function end
```

```
74 } //resetit function end
75
76 //highlight function. Inputs are the selected part and a boolean for hilite
77 * $scope.hilite = function (items, hilite) {
78   //
79   //iterate over each item that is used as an imported variable for the function using .forEach to look at each value that comes in the items input
80 *   items.forEach(function (item) {
81     //
82     //set the properties of the TML 3D Renderer to highlight the selected item using a TML Text shader. "green" is the name of the script for the TML
83     tml3dRenderer.setProperties(item, hilite === true ? { shader: "green", hidden: false, opacity: 0.9, phantom: false, decal: true }
84     : { shader: "Default", hidden: false, opacity: 1.0, phantom: false, decal: false });
85     }) //foreach function end
86 } //hilite function end
```

2. Navigate back to **Home** in the **Project** pane to view the **3D** canvas. Drag a **TML Text** widget onto the canvas. Change the **Studio ID** of the widget to *shaders*. Click the green edit icon next to the **Text** property to open the **Edit Text** box, and enter ONLY the code below, not the comments. Click **Done**. This code will allow the shader to be applied whenever the function is called in the script.

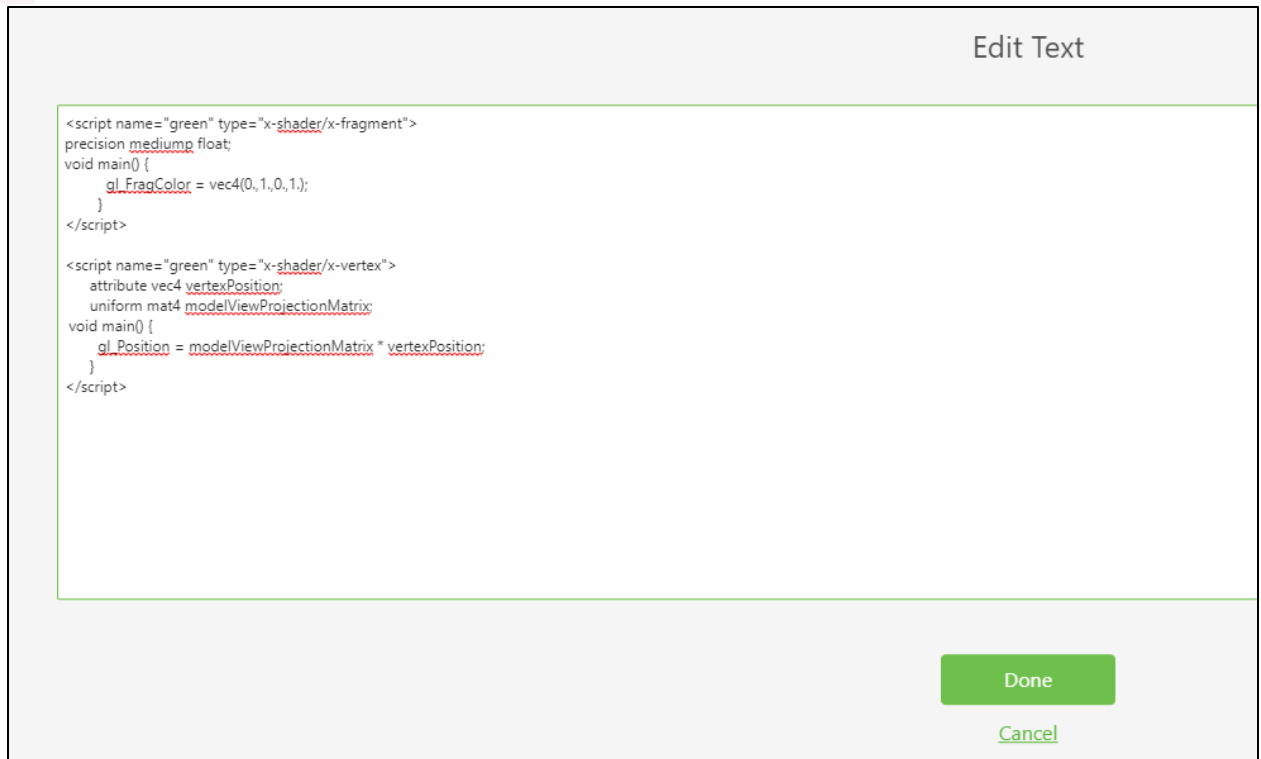

Note: The comments are only for explaining the code in this context. If included with the code, they will appear on the screen.

```
//name of the shader is green, the type is setting the color.
//
<script name="green" type="x-shader/x-fragment">
//
// setting the precision of the shader. medium is fine for this application.
precision mediump float;
//
// function to set the color of the shader. Syntax is vec4(R, G, B, A) format and the
values are on a 0.0-1.0 scale
void main() {
    gl_FragColor = vec4(0.,1.,0.,1.);
}
</script>
// name of the shader is green, this time the type sets the position
```

```

<script name="green" type="x-shader/x-vertex">
    attribute vec4 vertexPosition;
    uniform mat4 modelViewProjectionMatrix;
//
// sets the position of the vertex
void main() {
    gl_Position = modelViewProjectionMatrix * vertexPosition;
}
</script>

```

- Now that the function is set up, it is time to add it to the code to be called when a part is clicked on. In the `userpick` function after the popup, add the code below. This uses the `targetName` and `pathId` variables to determine which part has been clicked on by inputting the name of the model that was selected along with the selected part occurrence in the model to determine the highlighted portion. For example, if the front-left rotor is selected, `[targetName + "-" + pathId]` becomes `[quadcopter + "-" + /0/18/0/0]`, or `quadcopter-/0/18/0/0` if the string is written out. `True` sets the Boolean to be true so that the highlight shader is applied.

```

//
//highlight the chosen item and set the highlighter to true
$scope.hilite([targetName + "-" + pathId], true);

```

```

21     }); //end of ionic popup
22
23     //
24     //highlight the chosen item and set the shader to true
25     $scope.hilite([targetName + "-" + pathId], true);
26
27     // create a function to close the popup.

```

- Click **Save** and then **Preview** the experience to make sure that the shader works correctly. If a part turns green when clicked, then the shader has been successfully added.

5. Notice, that the shader does not disappear when the popup does. This will also be added to the code in **Home.js** so that the shader disappears in the same function. `refitems` will be added as an input to the `closePopup` function, and the `hilite` function will be called inside that function. This time the Boolean input will be set to `false`, thus turning off the shader. Add the additional code to the existing `closePopup` function.

Note: Make sure that `refitems` is added in as a new input for the `closePopup` function. Otherwise the experience will not work as intended.

```
// create a function to close the popup and turn off shading. popup is the popup,
refitems is the input for the part(s) that is being highlighted
var closePopup = function (popup, refitems) {
  //
  //The function returns a method for removing the popup from the screen and turns
off the shader
  return function () {
    //
    //using the input parts, set the hilite function to be false, removing the
shading
    $scope.hilite(refitems, false)
    //
    //apply the .close method, which removes a certain section of a selected
object, to the popup variable
    popup.close()
    //
    //change the Text property of the playButton to the instructionName variable,
which was created from the JSON data of the model
    $scope.view.wdg.playButton.text = instructionName;
    //
    /* create an object for the playButton called toPlay. This object will have
properties of model, which will be the name of the object that is clicked on and
instruction,
    which will add the proper syntax for calling a sequence, based off the
instructionName variable, into Studio*/
    $scope.view.wdg.playButton.toPlay = { model: targetName, instruction: '1-Creo
3D - ' + instructionName + '.pvi' };
    //
  } //return end
} // closepopup function end
```

```

27 // create a function to close the popup and turn off shading. popup is the popup, refitems is the input for the part(s)
28 var closePopup = function (popup, refitems) {
29 //
30 //The function returns a method for removing the popup from the screen and turns off the shader
31 return function () {
32 //
33 //using the input parts, set the hilite function to be false, removing the shading
34 $scope.hilite(refitems, false)
35 //
36 //apply the .close method, which removes a certain section of a selected object, to the popup variable
37 popup.close()
38 //
39 //change the Text property of the playButton to the instructionName variable, which was created from the JSON data
40 $scope.view.wdg.playButton.text = instructionName;
41 //
42 /* create an object for the playButton called toPlay. This object will have properties of model, which will be the
43 which will add the proper syntax for calling a sequence, based off the instructionName variable, into Studio*/
44 $scope.view.wdg.playButton.toPlay = { model: targetName, instruction: '1-Creo 3D - ' + instructionName + '.pvi' };
45 //
46 } //return end
47 } // closepopup function end

```

6. Click **Save** the **Preview** tab and view the experience now. If the shader disappears when the popup disappears, then this step has been completed successfully. The full code for this section is available in [Appendix 7](#). Save the project so that it can be used again to complete the following Metadata 202 tutorial.

Appendix 1: Sequence & Figured Related Vuforia Studio Events

Event Name (evt.name)	Description	Arguments/Usage Notes	Example
newStep	Triggered by going to a new step in an animation sequence	arg1 (text) of the following form: (<step #>/<total steps>) <step name>, e.g. "(4/8) Step 4 -remove case"	<pre>\$scope.\$on('newStep', function(evt, arg) { \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " evt: " + evt.name + " arg: " + arg ;});</pre>
playstarted	Triggered by play or play all of an animation sequence	No arguments returned	<pre>\$scope.\$on('playstarted', function(evt, arg) { \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " evt: " + evt.name;});</pre>
stepstarted	Similar to playstarted but with more flexible argument data returned	Arg1 is model name (e.g. "model-1") Arg2 is the type of object (twx-dt-model) Arg3 is an JSON object containing stepName,duration (in ms), acknowledge (boolean), totalSteps (int), nextStep (int). Note: Studio Preview for 8.3.2 now also includes stepDescription (the 'notes' from the step in Creo Illustrate) and acknowledgeMessage. However these two fields are not yet exposed for use in Vuforia View.	<pre>\$scope.\$on('stepstarted', function(evt, arg, arg2, arg3) { var parsedArg3 = JSON.parse(arg3); \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " evt: " + evt.name + " arg: " + arg + " arg2: " + arg2 + " arg3 fields: " + parsedArg3.stepName + " " + parsedArg3.duration + " " + parsedArg3.totalSteps ;});</pre>
playstopped	Triggered by stop of an animation sequence	arg1 (object) contains stepName,duration (in ms), acknowledge (boolean), acknowledgeMessage,totalSteps (int), nextStep (int)	<pre>\$scope.\$on('playstopped', function(evt, arg) { \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " evt: " +</pre>

			evt.name + " arg: " + arg.stepName ;});
stepstopped	Similar to playstarted but with more flexible argument data returned	See 'stepstarted'	Same as 'stepstarted' except with event name of 'stepstopped'
sequenceloaded	Triggered by sequence loading (when a model with a sequence is loaded, or the sequence property is updated for a model).	E.g. arg1 "model-1", arg2 is the type of object (twx-dt-model), arg3 is the model's current 'sequence' property (e.g. app/resources/Uploaded/mypvzfile/mysequence-name.pvi)	<pre>\$scope.\$on('sequenceloaded', function(evt, arg, arg2, arg3) { \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " evt: " + evt.name + " arg: " + arg + " arg2: " + arg2 + " arg3: " + arg3 ;});</pre>
sequenceacknowledge	Triggered by a figure/sequence that was defined in Creo Illustrate as having an acknowledgement	See 'playstopped'	Same as 'playstopped' except with event name of 'sequenceacknowledge'
sequencereset	Triggered by the model 'reset' (of the sequence/figure) event	Arg1 is model name (e.g. "model-1") Arg2 is the type of object (twx-dt-model)	<pre>\$scope.\$on('sequencereset', function(evt, arg, arg2) { \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " evt: " + evt.name + " arg1: " + arg + " arg2: " + arg2;});</pre>

Appendix 2: 3D Object Related Studio Events

Event Name (evt.name)	Description	Arguments/Usage Notes	Example
modelLoaded	Triggered when a model is loaded (can be multiple times if an experience includes multiple models) as well as when a model's	Arg1 is the model name (e.g. "model-1")	<pre>\$scope.\$on('modelLoaded', function(evt, arg) { \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " evt: " + evt.name + " arg: " + arg ;});</pre>

	'Resource' property is updated.		
Loaded3DObj	Triggered when any 3D widget is loaded in an experience. Similar to 'modelLoaded' event but applies to all 3D widgets.	See 'modelLoaded'	Same as 'modelLoaded' except with event name of 'loaded3DObj'
userpick	Triggered by users clicking on 3D objects in the experience (e.g. model items, models, 3D labels)	Arguments returned include event (name), target (e.g. model-1 or modelItem-1, or 3DImage-1, etc.), parent (null), edata (JSON object containing 'occurrence' property value for modelItems as defined in the PVZ, e.g. /0/0/18)	<pre>\$scope.\$on('userpick', function(event,target,parent,edata){ if (edata) { console.log('my console of userpick evt: ' + event.name + " target: " + target + " and parent:" + parent + " edata.occurrence: " + JSON.parse(edata).occurrence); } });</pre>
click	Similar to userpick	Event includes the widget's Studio ID in targetScope._widgetId. No args data returned.	<pre>\$scope.\$on('click', function(evt, arg) { \$scope.view.wdg['debug- label']['text'] = " evt: " + evt.name + " event targetScope Widget ID: " + evt.targetScope._widgetId;});</pre>
trackingacquired	Triggered when a ThingMark, Spatial, or Model Target is acquired ('locked onto' by Vuforia View)	Arg1 for ThingMark Targets is the ThingMark ID (e.g. 555:10), no arguments for other target types	<pre>\$scope.\$on('trackingacquired', function(evt, arg) { \$scope.view.wdg['label-1']['text'] = "evt: " + evt.name + " arg: " + arg ;});</pre>
trackinglost	Triggered when a ThingMark, Spatial, or Model Target is lost ('locked has been lost') by Vuforia View	See 'trackingacquired'	Same as 'trackingacquired' except with event name of 'trackinglost'

Appendix 3: ThingWorx External Data Services Studio Events

Event Name (evt.name)	Description	Arguments/Usage Notes	Example
--------------------------	-------------	-----------------------	---------

(servicename)-begin	Triggered by start of a TWX service defined in the Studio project	No arguments returned, just event.name.Note: event is broadcast to root scope, therefore must listen with \$scope.\$root.\$on, not just \$scope.\$on).	\$scope.\$root.\$on('myTWXService-begin', function(evt, arg) { \$scope.view.wdg['label-1']['text'] = \$scope.view.wdg['label-1']['text'] + " event name: " + evt.name;});
(servicename)-complete	Triggered by successful completion of a TWX service defined in the Studio project	See (servicename)-begin	See (servicename)-begin
(servicename)-end	Triggered by completion of a TWX service (whether successful or not)	See (servicename)-begin	See (servicename)-begin
(servicename)-failed	Triggered by failure when calling a TWX service	Returns arg that is JSON {service: logicalName, params: serviceParams, reason: reason}	

Appendix 4: Section 1 Code

```

$scope.$on('userpick', function (event, targetName, targetType, eventData) {
    //
    // variable to pull the value for the occurrence property in the eventData JSON object from the model
    var pathId = JSON.parse(eventData).occurrence

    // adds an ionic popup when a part is clicked. Show the pathId of the selected object
    var popup = $ionicPopup.show({
        template: '<div>' + pathId + ' </div>',
        scope: $scope
    }); //end of ionic popup

    // create a function to close the popup.
    var closePopup = function (popup) {
        //
        // function for returning that the popup will be closed using the .close() method
        return function() {
            //
            //close the popup
            popup.close()
        } // return end
    }

```

```

    } // closepopup function end

    //call the $timeout service which will call the function for closing the popup after 3 seconds (3000 ms)
    $timeout(closePopup(popup), 3000);

  }) //end brackets for userpick function. Will continue to move throughout code

```

Appendix 5: Section 2 Code

```

$scope.$on('userpick', function (event, targetName, targetType, eventData) {
  //
  //Look at model and see if it has metadata. If it does, then execute the below code and create an object called metadata
  PTC.Metadata.fromId(targetName)
    .then((metadata) => {
      //
      // variable to pull the value for the occurrence property in the eventData JSON object from the model
      var pathId = JSON.parse(eventData).occurrence

      // create variables based on attribute names from Creo Illustrate for this model. use metadata.get to obtain the data
      from the JSON properties for this occurrence.
      var partName = metadata.get(pathId, 'Display Name');
      var instructionName = metadata.get(pathId, 'Illustration');
      var partNumber = metadata.get(pathId, 'partNumber');

      // adds an ionic popup when a part is clicked. Show the part number and name of the selected object. &nbsp;<br> adds a
      line break between the two variables
      var popup = $ionicPopup.show({
        template: '<div>' + partNumber + '&nbsp;<br>' + partName + '</div>',
        scope: $scope
      }); //end of ionic popup

      // create a function to close the popup.
      var closePopup = function (popup) {
        //
        // function for returning that the popup will be closed using the .close() method
        return function() {
          //
          //close the popup
          popup.close()
        } // return end
      } // closepopup function end
    })
  });

```

```

    //call the $timeout service which will call the function for closing the popup after 3 seconds (3000 ms)
    $timeout(closePopup(popup), 3000);

  }) //end brackets for PTC API and .then
  //
  //catch statement if the promise of having a part with metadata is not met
  .catch((err) => { console.log('metadata extraction failed with reason : ' + err) })

}) //end brackets for userpick function. Will continue to move throughout code

```

Appendix 6: Section 3 Code

```

$scope.$on('userpick', function (event, targetName, targetType, eventData) {
  //
  //Look at model and see if it has metadata. If it does, then execute the below code and create an object called metadata
  PTC.Metadata.fromId(targetName)
    .then((metadata) => {
      //
      // variable to pull the value for the occurrence property in the eventData JSON object from the model
      var pathId = JSON.parse(eventData).occurrence

      // create variables based on attribute names from Creo Illustrate for this model. use metadata.get to obtain the data
      from the JSON properties for this occurrence.
      var partName = metadata.get(pathId, 'Display Name');
      var instructionName = metadata.get(pathId, 'Illustration');
      var partNumber = metadata.get(pathId, 'partNumber');

      // adds an ionic popup when a part is clicked. Show the part number and name of the selected object. &nbsp;<br> adds a
      line break between the two variables
      var popup = $ionicPopup.show({
        template: '<div>' + partNumber + '&nbsp;<br>' + partName + '</div>',
        scope: $scope
      }); //end of ionic popup

      // create a function to close the popup.
      var closePopup = function (popup) {
        //
        // function for returning that the popup will be closed using the .close() method
        return function() {
          //
          //close the popup
          popup.close()
          //
        }
      }
    })
  }
)

```

```

        //change the Text property of the playButton to the instructionName variable, which was created from the JSON data
of the model
        $scope.view.wdg.playButton.text = instructionName;
        //
        /* create an object for the playButton called toPlay. This object will have properties of model, which will be the
name of the object that is clicked on and instruction,
        which will add the proper syntax for calling a sequence, based off the instructionName variable, into Studio*/
        $scope.view.wdg.playButton.toPlay = { model: targetName, instruction: '1-Creo 3D - ' + instructionName + '.pvi' };
        //

} // playit function end

//sequenceloaded event listener triggers when the sequence property is updated
$scope.$on('sequenceloaded', function (event) {
    //
    // call a widget service to trigger the quadcopter model to play all steps for the given sequence
    twx.app.fn.triggerWidgetService('quadcopter', 'playAll');

```

```

}); //serviceloaded event function end

//resetit function
$scope.resetit = function () {
    //
    //set the sequence property of the quadcopter model to blank
    $scope.view.wdg.quadcopter.sequence = ''
} //resetit function end

//highlight function. Inputs are the selected part and a boolean for hilite
$scope.hilite = function (items, hilite) {
    //
    //iterate over each item that is used as an imported variable for the function using .forEach to look at each value that
    comes in the items input
    items.forEach(function (item) {
        //
        //set the properties of the TML 3D Renderer to highlight the selected item using a TML Text shader. "green" is the
        name of the script for the TML Text.
        tml3dRenderer.setProperties(item, hilite === true ? { shader: "green", hidden: false, opacity: 0.9, phantom: false,
        decal: true }
        : { shader: "Default", hidden: false, opacity: 1.0, phantom: false, decal: false });
    }) //foreach function end
} //hilite function end

```

Appendix 8: CAD Metadata API Functions ([from PTC support site](#))

Declaration	Parameters	Description
get (idpath, propName, categoryName)	<p>string string[] idpath—id path such as '/0/1', or array of id paths ['/0/1', '/0/2'].</p> <p>string string[] propName—(Optional) For example, 'Display Name' or ['Display Name', 'Part ID Path']</p> <p>string string[] categoryName—(Optional) For example, 'PROE Parameters'.</p>	<p>Gets a metadata object representing the id path or property value(s) for the given idpath and propName.</p> <p>This function returns the metadata object representing the given idpath, or if propName is given then the value of the property on the component.</p> <p>Example:</p> <pre>PTC.Metadata.fromId('model-1').then((metadata) => { var result = metadata.get('/0/6', 'Display Name') });</pre>

	<p>If propName was string [],  then categoryName must also be an array of matching length (or undefined).</p>	
getProp(propName, categoryName)	<p>string string[] propName—(Optional) For example, 'Display Name' or ['Display Name', 'Part ID Path']</p> <p>string string[] categoryName—(Optional) For example, 'PROE Parameters'.</p> <p>If propName was string [],  then categoryName must also be an array of matching length (or undefined).</p>	<p>This function returns all string property values from a single component, or undefined if no data/components available. If the given propName was an array, it returns string[] of values.</p> <p>Example:</p> <pre>PTC.Metadata.fromId('model-1').then((metadata) => { var result = metadata.get('/0/1').getProp('Display Name'); });</pre>
getCategory(categoryName)	<p>string} categoryName</p>	<p>This function returns object with all property names and values from given category.</p> <p>Example:</p> <pre>PTC.Metadata.fromId('model-1').then((metadata) => { var result = metadata.get('/0/6').getCategory('__PV_SystemProperties'); });</pre>
getSelected(selectFunc)	<p>function} selectFunc—(Optional) Function that controls the values put into the returned array. The function is given idpath and an argument and current metadata as:</p>	<p>This function returns an array of whatever is returned by the given selectFunc, or if selectFunc is undefined, then it returns string[] of id paths.</p> <p>Example:</p> <pre>PTC.Metadata.fromId('model-1').then((metadata) => { var selectFunc = function(idpath) { return metadata.get(idpath, 'Display Name'); }; });</pre>

	<pre>`this` function(idpath) { return [idpath, this.get(idpath, 'Display Name')]]; });</pre>	<pre> } var result = metadata.getSelected(selectFunc); });</pre>
find (propName, category)	<p>string} propName—(Required)</p> <p>string} category—(Optional)</p>	<p>Finds components based on property values. Also see findCustom below.</p> <p>Returns a finder for components based on given the propName and category.</p> <p>Example:</p> <pre>PTC.Metadata.fromId('model-1').then((metadata) => { var displayName = metadata.find('Display Name').like('BOLT'); }); PTC.Metadata.fromId('model-1').then((metadata) => { var result = metadata.find('Part Depth').lessThan(3).find('Display Name').like('PRT'); }); PTC.Metadata.fromId('model-1').then((metadata) => { var selectFunc = function(idpath) { return metadata.get(idpath, 'Display Name') var result = metadata.find('Part Depth').greaterThan(4, selectFunc) }); });</pre> <p>The comparison can be as follows:</p> <ul style="list-style-type: none"> - startsWith, like, sameAs, unlike : string comparison - equal, notequal, greaterThanEq, lessThanEq, lessThan, greaterThan : numeric comparison - in, out : numeric range comparison - before, after : date/time comparison
findCustom (whereFunc, selectFunc)	<p>function} whereFunc—(Required)</p> <p>function} selectFunc—(Optional)</p>	<p>Also see find above.</p> <p>This function returns a finder for components based on custom whereFunc. The following example finds all components with depth<2 or has a name like 'ASM'.</p> <p>Example:</p>

		<pre>PTC.Metadata.fromId('model-1').then((metadata) => { var whereFunc = function(idpath) { const depth = metadata.get(idpath, 'Part Depth') const name = metadata.get(idpath, 'Display Name') return parseFloat(depth) >= 4 (name && name.search('ASM') >= 0) } var result = metadata.findCustom(whereFunc); });</pre>
